RESEARCH EXPERIENCE:

Synthesis of metal nanoparticles (monolayer-protected clusters) coated with alkanethiols, alkylamines and weak ligands (surfactants) comprised into films in order to be used as chemiresistive sensors. Recent terrorist attacks have imposed more pressure on the design of sensors able to detect explosive vapors. These sensors should be small, fast in response, reproducible, sensitive and easy to fabricate. Part of my research focus on the miniaturization of conventional films (cm-mm) to micro- and nano-scopic films. Besides practical benefits as portability and reduced cost, fundamental studies on the vapor and gas sensing behavior are of relevant interest as well. Other area of research is focused on the design of hydrogen (H₂) sensors. Hydrogen is thought to be one of the main sources of energy in the future, however, is highly explosive when mixed with air. This sensor is based on Pd nanoparticles use as catalyst for the reaction with hydrogen gas. Just recently we are designing ethanol and methanol sensors with potential industry applications for detection of alcohol (breathalyzers) and fuel-cell technology, respectively.
